March 13, 2016
Proposes three new heuristics for Sparse Discriminant Analysis (SDA) by using the following techniques: proximal gradient method, accelerated proximal gradient method and alternating direction method of multipliers.

Outline:

- Review of linear discriminant analysis.
- Our proximal heuristics for SDA.
- Numerical results.
The Classification Problem

Given \( n \) observations \( x_i \in \mathbb{R}^p \). Stored as matrix \( X \in \mathbb{R}^{n \times p} \).

Each \( x_i \) belongs to exactly one of \( K \) classes \( C_1, C_2, \ldots, C_K \).

Problem: Design a decision rule to assign new observations to exactly one of the \( K \) classes.
Linear Discriminant Analysis (LDA) is a technique for supervised classification where data is linearly projected to a subspace where class discrimination is maximized using a set of discriminant vectors $\beta_1, \beta_2, \ldots, \beta_q \in \mathbb{R}^p, q < K$.

There are three equivalent approaches that result in the LDA classifier:

1. The multivariate Gaussian model
2. Fisher’s discriminant problem
3. The optimal scoring problem
**Optimal Scoring**

**Idea:** Turns categorical variables (class labels) into quantitative ones (class score).

Suppose we know \( \{(\theta_\ell, \beta_\ell)\}_{i=1}^{k-1} \). Find \((\theta_k, \beta_k)\) by solving

\[
\min_{\beta_k, \theta_k} \| Y \theta_k - X \beta_k \|^2
\]

subject to

\[
\frac{1}{n} \theta_k^T Y^T Y \theta_k = 1
\]

\[
\theta_k^T Y^T Y \theta_\ell = 0 \quad \forall \ell < k
\]

- \( Y \) is an \( n \times K \) indicator matrix for class membership,
- \( X \) is an \( n \times p \) data matrix,
- \( \beta_k \) is the \( k^{th} \) discriminant vector in \( \mathbb{R}^p \), and
- \( \theta_k \) is the \( k^{th} \) scoring vector in \( \mathbb{R}^k \).
Challenges in LDA

LDA is known to fail in the following cases:

1. When data is in a high-dimensional setting, meaning when the number of predictor variables $p$ is larger than the number of observations $n$.

2. When linear boundaries are unable to separate the classes.
Sparse Discriminant Analysis

**Clemmensen et al. 2011**: Take the Optimal Scoring formulation of LDA and applies an elastic net penalty to the coefficient vectors.

\[
\begin{align*}
\min_{\beta_k, \theta_k} & \quad \| Y\theta_k - X\beta_k \|^2 + \gamma \beta_k^T \Omega \beta_k + \lambda \| \beta_k \|_1 \\
\text{s.t.} & \quad \frac{1}{n} \theta_k^T Y^T Y \theta_k = 1 \\
& \quad \theta_k^T Y^T Y \theta_\ell = 0 \quad \forall \ell < k
\end{align*}
\]

- \( \gamma, \lambda \) are non-negative tuning parameters and \( \Omega \) is a positive definite matrix.
- The \( \ell_1 \) term encourages sparsity and the \( \Omega \) term encourages smoothness.

SDA is **not convex** in \( \beta \) and \( \theta \) jointly.
For $\beta_k$ fixed, SDA is a least squares problem:

$$\min_{\theta} \left\{ \| Y\theta - X\beta_k \|^2 : \theta^T D\theta = 1, \theta^T D\theta_\ell = 0 \quad \forall \ell < k \right\}$$

where $D := \frac{1}{n} Y^T Y$.

Closed form solution is given by

$$\theta_k = r(I - Q_k Q_k^T D)D^{-1}Y^T X\beta_k$$

where $Q_k = [\theta_1|\theta_2|\ldots|\theta_{k-1}|e]$, $e$ is the all-ones vector, $I$ is the identity matrix, and $r$ is a proportionality constant.
For $\theta_k$ fixed, SDA becomes
\[
\min_{\beta} \| Y\theta_k - X\beta \|^2 + \gamma \beta^T \Omega \beta + \lambda \| \beta \|_1.
\]
This is a convex problem in $\beta$! We propose several proximal methods:

1. **Proximal Gradient Method (PGM)**
2. **Accelerated Proximal Gradient Method (APGM)**
3. **Alternating Direction Method of Multiplication (ADMM)**
Decompose objective as $f(\beta) + g(\beta)$ where

- $f(\beta) = \frac{1}{2} \beta^T A \beta - \beta^T d$ with $A = 2(X^T X + \gamma \Omega)$, $d = 2\theta_k^T Y^T X$, and
- $g(\beta)) = \lambda \|\beta\|_1$.

Taking a gradient step with respect to $f$, giving us

$$p^t = \beta^t - \alpha \nabla f(\beta^t) = \beta^t - \alpha (A \beta^t + d)$$

Then, we take proximal step with respect to $g$, giving us

$$\beta^{t+1} = \text{sign}(p^t) \max\{|p^t| - \lambda \alpha e, 0\} = S_{\lambda \alpha}(p^t)$$

where $\alpha > 0$ is a fixed step size.
Accelerated Proximal Gradient Method (APGM): A version of PGM that adds a momentum term in order to accelerate convergence.

Results are generated by the following iterates:

1. \( y^{t+1} = \beta^t - \omega_t (\beta^t - \beta^{t-1}) \)
2. \( p^t = y^{t+1} - \alpha \nabla f(\beta^t) = \beta^t - \alpha (A\beta^t + d) \)
3. \( \beta^{t+1} = \mathbf{S}_{\lambda\alpha}(p^t) \)

where \( \omega_t \in [0, 1) \) is an extrapolation parameter, a standard choice for \( \omega_t \) is \( \frac{t}{t+3} \).
ADMM

Alternating Direction Method of Multipliers (ADMM): Algorithm that blends dual decomposition and augmented Lagrangian for solving constrained optimization problems.

By splitting $\beta$ as $\beta = x = y$, we can form the Augmented Lagrangian:

$$L_\delta(x, y, z) = \frac{1}{2} x^T A x - x^T d + \lambda \| y \|_1 + z^T (x - y) + \frac{\delta}{2} \| x - y \|^2$$

where $\delta$ is a nonnegative penalty parameter.

Using ADMM will generate a sequence of iterates $\{x, y, z\}$ by

1. $x^{t+1} = (\delta I + A)^{-1} (d + \delta y^t - z^t)$
2. $y^{t+1} = S_\lambda (x^{t+1} + \frac{z^t}{\delta})$
3. $z^{t+1} = z^t + \delta(x^{t+1} - y^{t+1})$. 
Numerical Experiments

We performed a series of numerical experiments using Matlab2014a through UA’s cluster RC2 to compare classification performance of the following heuristics:

1. Proximal Gradient Method for SDA (SDAP)
2. Accelerated Proximal Gradient Method for SDA (SDAAP)
3. Alternating Direction Method of Multipliers for SDA (SDAD)
4. Sparse Zero Variance Discriminant Analysis (SZVD)
5. Sparse Discriminant Analysis (SDA).

We used cross-validation to train parameters.
Time Series Data

- **Penicillium (Pen)** data set of multi-spectral imaging of 3 Penicillium that are almost visually indistinguishable \( (p = 3542, \ k = 3, \ n = 36, \ \text{training size} = 24, \ \text{testing size} = 12) \) (Clemmensen, 2007).

- **Electrocardiogram measurements (ECG)** data set of 884 heartbeat signals that were either classified as healthy or unhealthy \( (p = 136, \ k = 2, \ n = 884, \ \text{training size} = 23, \ \text{testing size} = 861) \).

- **Coffee data set** consists of 56 food spectrogram observations of either Arabica or Robusta variants of instant coffee \( (p = 286, \ k = 2, \ n = 56, \ \text{training size} = 28) \).

- **Olive Oil data set** of 60 food spectrogram observations of extra virgin olive oil that originated in 1 of 4 countries \( (p = 570, \ k = 4, \ n = 60, \ \text{training size} = 30) \) (E. Keogh, X.Ci, L.Wei, and C.A. Ratanamahatana, 2006).
Synthetic Data Experiments

- Sample observations from multivariate Normal distributions.
- Different classes had different means, but same covariance matrix.
- We also varied each set of data based upon its constant covariance ($r \in \{0, 0.1, 0.5, 0.9\}$).

We have developed three new heuristics which apply the following techniques for solving the SDA problem: ADMM, PGM, and APGM.

Work in progress

- Developing R and Matlab packages of heuristics
- Deriving bounds on classification error
- Analyzing convergence
Thank You!
